## END OF CHAPTER EXERCISES

# Chapter 18 : Pricing Interest Rate Derivatives 

Financial Engineering : Derivatives And Risk Management

(Keith Cuthbertson, Dirk Nitzsche)

1. Why might you use Black's model to price a 1-year option on a T-bond where the underlying bond is a 15-year T-bond, but not where the underlying bond is a 1 -year Tbond?
2. Price the following swaption using Black's model. The swaption is a 4-year swap, starting in 3 years, payments are annual and the principal in the swap is $\$ 100,000$. The volatility of the swap rate is $20 \%$ p.a. It is a payer swaption with a strike (swap) rate of $7.5 \%$. The yield curve is currently flat at $8 \%$ (continuous compounding).
3. Intuitively, how is the one-period interest rate lattice, in the no-arbitrage approach, consistent with the observed term structure of interest rates and their volatility? (Assume volatility is the same for all one-period rates in the lattice).
4. What advantages does a trinomial lattice have over a binomial lattice when used in pricing interest rate derivatives?

## Data for Questions 5, 6 and 7

You are given the following data to be used in answering Q5-Q7. The interest rate lattice over 3 periods is:

|  |  | $16 \%$ |  |
| :--- | :--- | :--- | :--- |
|  |  |  | $(0.216)$ |
|  |  | $14 \%$ |  |
|  |  | $12 \%$ | $(0.36)$ |
|  | $(0.6)$ |  | $13 \%$ |
|  |  | $10 \%$ | $(0.432)$ |
|  | $8 \%$ | $(0.48)$ | 9.0 |
|  | $(0.4)$ |  | $(0.288)$ |
|  |  | $7 \%$ |  |
|  |  | $(0.16)$ | $6 \%$ |
|  |  |  | $(0.064)$ |

The risk neutral probability of an 'up' move is $q=0.6$ and for a 'down' move is $(1-q)=0.4$. The figures in parenthesis are the probability of reaching each node, times the number of ways to reach that node. They are therefore the BOPM terms :

$$
\mathrm{q}_{k}^{n}=\binom{n}{k} q^{k}(1-q)^{n-k}
$$

Hence for $\mathrm{n}=2$, and $\mathrm{k}=1$ 'up' moves, we are at the node 'ud' (or equivalently 'du')
and

$$
\begin{array}{ll}
\text { and } & q_{1}^{n}=q_{u d}^{n}=\binom{2}{1}(0.6)^{1}(0.4)^{1}=0.48 \\
\text { similarly } & q_{2}^{n}=q_{u u}^{n}=\binom{2}{2}(0.6)^{2}(0.4)^{0}=0.36
\end{array}
$$

5. What is the price of a two-year European cap with $\mathrm{K}_{\mathrm{c}}=10 \%$ ?
6. How would your analysis in pricing the 2-year cap change, if the cap were an American style option?
7. What is the 'price' (i.e. the FRA rate) for a 2 -year FRA, where the actual cash payout occurs at $\mathrm{t}=3$ ? This is sometimes called a 'delayed settlement FRA'.
