Modeling of a Tennis Ball Server

• Definition of a Projectile:

- » A projectile is a fired, thrown, or otherwise projected object, such as a bullet, having no capacity for self propulsion
- » In the absence of a propulsion force, the only force acting on an idealized projectile is gravity
- » Additional forces – due to drag, lift and wind – will also be present and may or may not be significant

Ahmed Kovacevic, City University London

Modeling of a Tennis Ball Server

• Choice of Projectile:

- » Neglecting drag, lift and wind should work well for typical projectile unless the problem involves a low mass or high cross-sectional area projectile
- » Consider the drag force on a ping pong ball (immediately after launch; assuming a launch velocity of 9.5 m/s):

$$F_d = C_d \rho A v^2$$

$$F_d = (1/2)(1.21 \text{ kg/m}^3)[\pi(0.038/2)^2](9.5 \text{ m/s})^2$$

$$= 0.062 \text{ kg} \cdot \text{m/s}^2 = 0.062 \text{ N}$$

- » Consider the force in light of the mass (0.0025 kg = 2.5 g) of a ping pong ball
- » Using $F = ma$: $0.062 \text{ N} = 0.0025 \cdot a$
 $a = 24.8 \text{ m/s}^2 \gg 9.81 \text{ m/s}^2$

Ahmed Kovacevic, City University London

Basic Projectile Motion Equations

Commonly Used Projectile Equations (in x-y coordinate system)

Coordinate Direction:	x	y
Acceleration:	$a_x = 0$	$a_y = -g$ where, $g = 9.81 \text{ m/s}^2$
Velocity:	$v_x = v_{0x} = \text{const}$	(2) $v_y = v_{0y} - gt$
Position:	(1) $x = x_0 + v_x t$	(3) $y = y_0 + v_{0y} t - 1/2 gt^2$
Additional equation:		(4) $v_y^2 = v_{0y}^2 - 2g(y - y_0)$
Calculating v_{0x} and v_{0y} given v_0 and θ_0 .		(5) $v_x = v_0 \cos \theta$ (6) $v_{0y} = v_0 \sin \theta$

Ahmed Kovacevic, City University London

Projectile Motion Calculation

Determining Values v_0 or θ Needed to Strike a Target

Method A: Set your launcher at a fixed launch angle, θ . Calculate the launch velocity, v_0 , needed to strike a target located at an arbitrary (x,y) position:

First write position equations:

$$(a) \ x = x_0 + v_0(\cos \theta)t \quad (b) \ y = y_0 + v_0(\sin \theta)t - 1/2 gt^2$$

Let $L = (x - x_0)$ and $h = (y - y_0)$, solve (a) to get

$$(c) \ v_0 t = \frac{L}{\cos \theta} \quad \text{sub this into (b):} \quad h = \sin \theta \left(\frac{L}{\cos \theta} \right) - \frac{1}{2} gt^2$$

$$\text{Solve for } t: \quad (d) \quad t = \sqrt{\frac{2(L \tan \theta - h)}{g}}$$

Substitute t into equation (c) and solve for v_0 :

$$(e) \quad v_0 = \frac{L}{\cos \theta} \sqrt{\frac{g}{2(L \tan \theta - h)}}$$

Ahmed Kovacevic, City University London

Projectile Motion Calculation

Determining Values of v_0 or θ Needed to Strike a Target

Method B: If your launcher can fire only at discrete values of v_0 , select an appropriate v_0 and calculate the precise angle θ needed to strike a target located at (x,y): First write position equations:

$$(a) \ x = x_0 + v_0(\cos \theta)t \quad (b) \ y = y_0 + v_0(\sin \theta)t - 1/2 gt^2$$

$$\text{Let } L = (x - x_0) \text{ and } h = (y - y_0), \text{ solve (a) to get: } (c) \ t = \frac{L}{v_0 \cos \theta}$$

$$\text{Substitute (c) into (b):} \quad h = v_0 \sin \theta \left(\frac{L}{v_0 \cos \theta} \right) - \frac{1}{2} g \left(\frac{L}{v_0 \cos \theta} \right)^2$$

Using $\sin \theta / \cos \theta = \tan \theta$ and the identity $(1/\cos \theta)^2 = \sec^2 \theta = \tan^2 \theta + 1$

$$\text{We obtain (d)} \quad \tan^2 \theta - \frac{2v_0^2}{gL} \tan \theta + \frac{2v_0^2 h}{gL^2} + 1 = 0$$

This is a quadratic equation of the form $au^2 + bu + c$, where $u = \tan \theta$. The two roots correspond to the two launch angles ($\theta_1 = \tan^{-1} u_1$ and $\theta_2 = \tan^{-1} u_2$) which may be used to reach the same target.

Projectile Example

Example 1: Projectile Heuristics

A "heuristic" is a "rule-of-thumb." The objective of this example is to use some simple numbers to help the learner to more easily estimate approximately what speeds might be necessary for a launched projectile.

Determine, for level ground,

- (1) The launch angle that gives the maximum distance;
- (2) The corresponding launch velocity;
- (3) The maximum height of the trajectory.

Equation summary: (a) Optimal angle: $\theta = 45^\circ$
 (b) Minimum launch velocity to strike a target: $v_0 = \sqrt{gL}$
 (c) Maximum height of the projectile: $y_{\max} = L/4$

(1) To find the launch angle that gives the maximum distance (on level ground), first write position equations. (Let $L = (x - x_0)$ and $h = (y - y_0) = 0$.)

(a) $L = v_0 \cos \theta t$ (b) $h = 0 = v_0 \sin \theta t - 1/2 g t^2$

Divide (b) by t to get: (c) $0 = v_0 \sin \theta - 1/2 g t$

Rearrange (c) to get the landing time: $t_{\text{land}} = (2v_0 \sin \theta) / g$

Substitute t_{land} into (a) to get $L = (2v_0^2 / g) \sin \theta \cos \theta$

Since $\cos \theta \sin \theta = (\sin 2\theta) / 2$, for level ground we can calculate the landing distance L from:

$$L = (v_0^2 / g) \sin 2\theta$$

Since $\sin 2\theta$ is maximized at $2\theta = 90^\circ$, L is therefore maximum at $\theta = 45^\circ$. Specifically, $L = (v_0^2 / g)$.

Projectile Example

Example 1: Projectile Heuristics

A "heuristic" is a "rule-of-thumb." The objective of this example is to use some simple numbers to help the learner to more easily estimate approximately what speeds might be necessary for a launched projectile.

Determine, for level ground,

- (1) The launch angle that gives the maximum distance;
- (2) The corresponding launch velocity;
- (3) The maximum height of the trajectory.

Equation summary: (a) Optimal angle: $\theta = 45^\circ$
 (b) Minimum launch velocity to strike a target: $v_0 = \sqrt{gL}$
 (c) Maximum height of the projectile: $y_{\max} = L/4$

(2) The minimum launch velocity to reach a target (on level ground) at a distance L is:

$$v_0 = \sqrt{gL} \quad \text{From } v_0 = \frac{L}{\cos \theta} \sqrt{\frac{g}{2(L \tan \theta - h)}}$$

(3) The maximum height, $y_{\max}$, of the trajectory is found as follows: (Recall that at $y_{\max}$, $v_y = 0$)

$$v_y^2 = 0 = (v_0 \sin \theta)^2 - 2g(y_{\max} - 0)$$

Solve for $y_{\max}$: $y_{\max} = (v_0 \sin \theta)^2 / 2g$

If $\theta = 45^\circ$, $\sin 45 = \sqrt{2}/2$, and $(\sin 45)^2 = 1/2$. also note that $v_0^2 = gL$.

Finally, $y_{\max} = L/4$

Projectile Example

Example 1: Projectile Heuristics

A "heuristic" is a "rule-of-thumb." The objective of this example is to use some simple numbers to help the learner to more easily estimate approximately what speeds might be necessary for a launched projectile.

Determine, for level ground,

- (1) The launch angle that gives the maximum distance;
- (2) The corresponding launch velocity;
- (3) The maximum height of the trajectory.

Equation summary: (a) Optimal angle: $\theta = 45^\circ$
 (b) Minimum launch velocity to strike a target: $v_0 = \sqrt{gL}$
 (c) Maximum height of the projectile: $y_{\max} = L/4$

A simple numerical example: (These are "ballpark" numbers): A slow pitch softball pitcher wishes to hit home plate (approximately 15 m away) with a pitch with minimum effort. Assume no drag and that he releases the ball close to ground level ($h = 0$) very near the pitching rubber.

The optimal angle is 45° .

Minimum velocity $v_0 = \sqrt{gL} = \sqrt{9.81 \cdot 15} = \sqrt{147} = 12.1 \text{ m/s}$.

The height of the trajectory would be $L/4 = 15/4 = 3.75 \text{ m}$.

Work-Energy to Produce Desired V_0

The Work-Energy equation:

$$\Sigma U_{1-2} = T_2 - T_1$$

Where,

T_1, T_2 - Initial and final Kinetic Energy of the projectile

$T_1 = 0$

$T_2 = mv^2/2$

ΣU_{1-2} - work done on the projectile while in the launcher.

Recall: work = force x distance

Work done on the projectile is sum of:

- Work of the spring: $U_s = +kd^2/2$
- Gravity: $U_g = -mg(d \sin \theta)$
- Friction - not estimated

$\Sigma U_{1-2} = T_2 - T_1$

$$kd^2/2 - mg(d \sin \theta) - \text{Friction} = 1/2 mv^2 + \text{KE (of spring, mechanism)}$$

Ahmed Kovacevic, City University London

Work-Energy Example

Determine spring stiffness, k
Determine deflection needed to strike an 8m target with a 55g projectile.
Neglect friction and kinetic energy imparted to mechanism.

Schematic of Launcher;
 d = spring deflection
 $d \sin \theta$ = change in elevation of projectile

(1) Spring Stiffness (Spring from a hardware store)
5kg load will compress the spring for 17.5 mm; Therefore, $k_{sp} = 2.8 \text{ N/mm} = 2.8 \text{ kN/m}$

(2) From previous chart: ($v_0 = 9.2 \text{ m/s}$, $\theta = 56^\circ$) to strike 8 m target

(3) Given values:

(a) Mass	= 55 g = 0.055 kg
(b) Velocity	= 9.2 m/s

Ahmed Kovacevic, City University London

Work-Energy Example

(4) Write work-energy equation:

$$T_1 + \Sigma U_{1-2} = T_2$$

$$kd^2/2 - mg(d \sin \theta) = mv^2/2$$

$$2.8 d^2/2 - 0.055 \cdot 9.81 \sin 56^\circ d - 0.055 \cdot 9.2^2/2 = 0$$

This is a quadratic equation:
 $1400d^2 - 0.447d - 2.327 = 0$, of the form $ad^2 + bd + c = 0$

Use the quadratic equation yields roots $d_{1,2} = 0.04 \text{ m}$

(5) Result:
The launcher spring needs to compress for 40 mm in order to propel a 55g projectile out of the launcher with a velocity of 9.2 m/s.
This is for a spring with $k_{sp} = 2.8 \text{ N/mm}$.

Schematic of Launcher;
 d = spring deflection
 $d \sin \theta$ = change in elevation of projectile

Ahmed Kovacevic, City University London

Work-Energy Example

(6) Caution
This is only approximate value since friction and kinetic energy of the launch mechanism are neglected. However, this gives an idea of how to select a spring or other mechanism for achieving launch of the ball.

(7) Velocity
To achieve accurate launch one needs to adjust velocity accurately.
If a launch to the distance of 8.5 m is required.
At the launch angle of 56° the required velocity is 9.48 m/s. The calculation yields a spring deflection of 41.5mm, only 1.5 mm more than needed for the first example.

Note: This is difficult to achieve!

Ahmed Kovacevic, City University London

Summary

- For modeling purposes:
 - » Find range of velocities and angles necessary to get tennis ball to the targets
 - » Next, depending on your chosen design, determine how you will supply the necessary initial velocity
 - » Consider drag effects as well
